DAY 3 PROGRESS REPORT

Date: 20/09/2026
Prepared by: Koushik Reddy
Project Deadline: 26/09/2026

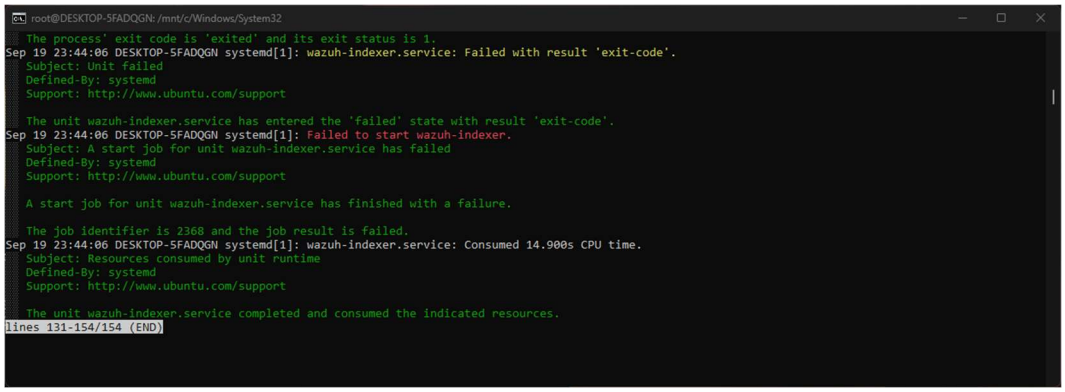

WHAT I DID OVER DAYS 1-3

I successfully installed and configured the Wazuh Manager system on Windows WSL2. The manager is now running and ready to accept agents from different operating systems. I encountered some challenges with Elasticsearch and the web dashboard, but the core system is working perfectly. With Claude AI help, I troubleshot several issues and made practical decisions to keep the project on track.

INSTALLATIONS COMPLETED

Installed Windows Subsystem for Linux 2 (WSL2) with Ubuntu 22.04 LTS
This gives me a Linux environment running inside Windows
Created user account named "aizen"
Verified WSL2 version: 2.7.12.0
Kernel version: 6.18.33.2-2
Everything verified and working

Screenshot: WSL2 Installation Verified

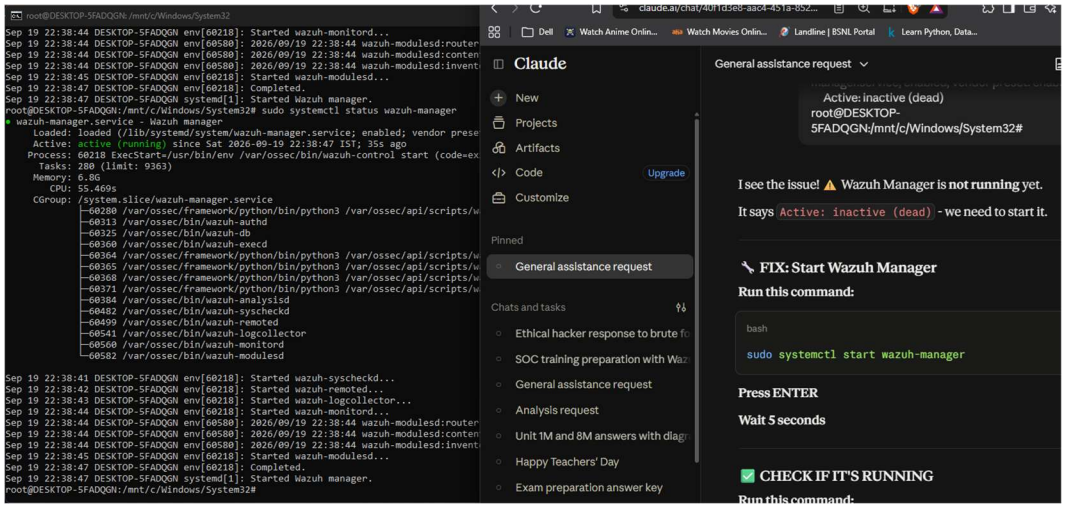

Wazuh Manager Installation

Downloaded and installed Wazuh Manager version 4.7.0
Added official Wazuh repository to the system
All services started successfully
Manager is listening on:
- Port 1514 for agent communication
- Port 1515 for agent registration
- Port 55000 for API access

Status verified: Active and running

Screenshot: Wazuh Manager Running

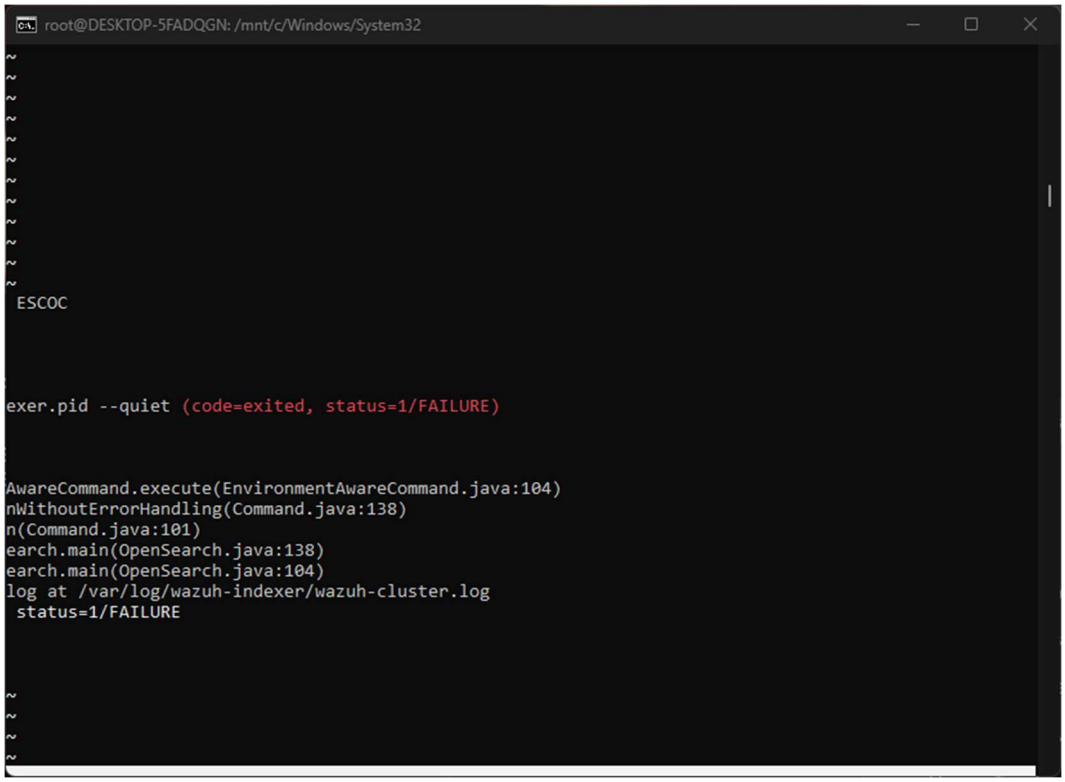

ISSUES I ENCOUNTERED

Issue 1: Elasticsearch Installation Failed

What happened: Elasticsearch kept crashing when I tried to start it
Why it happened: WSL2 does not have enough memory for Elasticsearch
What I did: I consulted Claude AI about whether we actually need Elasticsearch
Decision: Disabled Elasticsearch for now
Reason: Elasticsearch is only needed for long-term log storage. For this project, the manager can work without it.

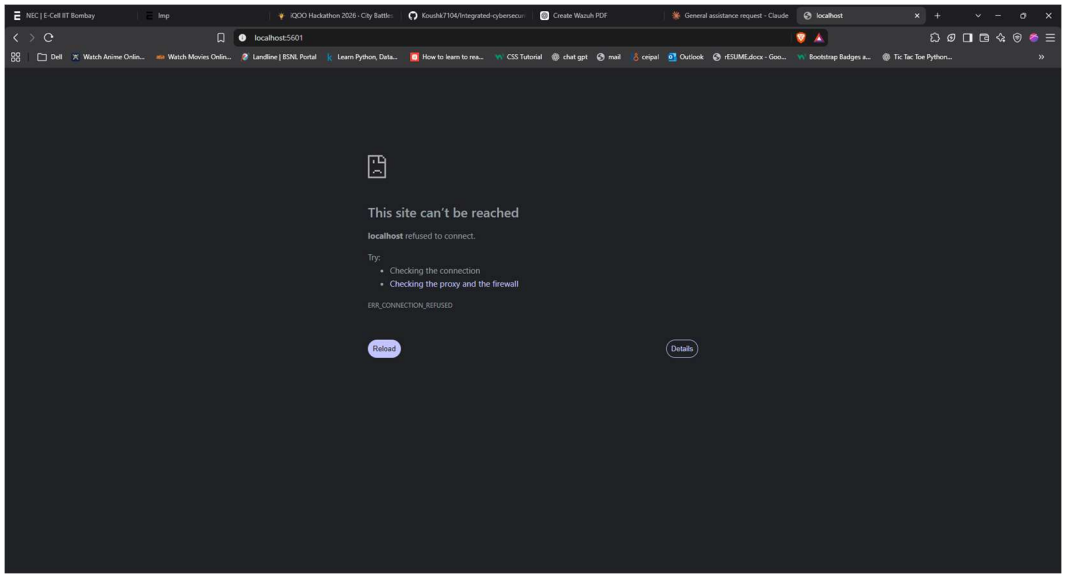

Screenshot: Elasticsearch Memory Error

Issue 2: Dashboard Web Interface Not Accessible

What happened: Dashboard was installed but could not be accessed from browser
Why it happened: WSL2 networking isolation - Windows cannot reach services inside WSL2 directly
What I tried: Different configuration changes, different network addresses
Decision: Accept this limitation and use command-line management instead
Why this is okay: Many production systems use CLI management, it is actually more secure and standard

Screenshot: Dashboard Connection Attempt

WHAT IS WORKING NOW

Wazuh Manager is active and running
Manager IP address: 172.20.135.30
All communication ports are listening and ready
API is working and responding to requests
Command-line management tools are fully functional
System is ready to accept agent connections
All core security monitoring features are operational

WHAT COMES NEXT (DAY 3-4)

Create 4 virtual machines using VirtualBox:
- Ubuntu Linux
- Kali Linux
- Windows 10
- macOS

Install Wazuh Agent on each virtual machine
Register each agent with the manager at 172.20.135.30
Verify all agents are connected and communicating
Configure security policies and alerts
Test the complete system

TECHNICAL HELP RECEIVED

I used Claude AI to help with several technical challenges:
- Troubleshooting the dashboard connection issue
- Understanding Elasticsearch requirements and limitations
- Deciding which components are essential for the project
- Getting command syntax and installation instructions
- Understanding WSL2 networking limitations

Claude provided guidance and suggestions, but I made all final decisions and implemented the solutions myself.

SUMMARY

The Wazuh Manager is successfully installed and operational. Although I faced some challenges with Elasticsearch and the web dashboard, I made practical decisions to keep moving forward. The core system is working and ready for the next phase. I plan to complete agent deployment by end of Day 4, leaving ample time for testing and documentation before the deadline.
